

AI Assisted Coding

Assignment - 02

Name : D.udayan

Roll No : 2303A54017

Batch : 48

Lab 2: Exploring Additional AI Coding Tools beyond Copilot – Gemini (Colab) and Cursor AI

Task 1: Statistical Summary for Survey Data

† Scenario: You are a data analyst intern working with survey responses stored as numerical lists.

- **Prompt used :**

"Write a Python function that takes a list of numbers and returns the mean, minimum, and maximum values."

- **Generated code :**

```
import statistics def
analyze_numbers(numbers):
    """
```

Calculates the mean, minimum, and maximum of a list of numbers.

Args:

numbers (list): A list of numerical values.

Returns:

tuple: A tuple containing (mean, minimum, maximum).

Returns (None, None, None) if the list is empty.

""" if not

numbers:

return None, None, None mean_value =

statistics.mean(numbers) min_value =

min(numbers) max_value =

max(numbers) return mean_value,

min_value, max_value

Example Usage

```
data = [10, 20, 30, 40, 50] mean, minimum,
maximum = analyze_numbers(data) print(f"List:
{data}") print(f"Mean: {mean}") print(f"Minimum:
{minimum}") print(f"Maximum: {maximum}")
data_empty = [] mean_empty, min_empty, max_empty =
analyze_numbers(data_empty) print(f"\nList: {data_empty}")
```

```

print(f"Mean: {mean_empty}")
print(f"Minimum: {min_empty}")
print(f"Maximum: {max_empty}")

```

- **Sample Output :**

List: [10, 20, 30, 40, 50] Mean: 30 Minimum: 10 Maximum: 50

List: [] Mean: None Minimum: None Maximum: None

- **Short Explanation of Logic :**

The **mean** represents the average of a set of numbers. It is obtained by adding all the values in the list and dividing the sum by the total number of elements.

The **minimum value** is the smallest number present in the list, and the **maximum value** is the largest number present in the list. These values are calculated using Python's built-in `min()` and `max()` functions.

The function accepts a list of numerical values as input, computes the mean, minimum, and maximum values, and displays them as a statistical summary of the given data.

The screenshot shows a Google Colab notebook titled "AI_LAB2.ipynb". The code cell contains the following Python function:

```

import statistics

def analyze_numbers(numbers):
    """
    Calculates the mean, minimum, and maximum of a list of numbers.

    Args:
        numbers (list): A list of numerical values.

    Returns:
        tuple: A tuple containing (mean, minimum, maximum).
               Returns (None, None, None) if the list is empty.
    """
    if not numbers:
        return None, None, None

    mean_value = statistics.mean(numbers)
    min_value = min(numbers)
    max_value = max(numbers)

    return mean_value, min_value, max_value

```

Below the function definition, there is an "Example Usage" section:

```

data = [10, 20, 30, 40, 50]
mean, minimum, maximum = analyze_numbers(data)
print("List: (data)")
print("Mean: (mean)")
print("Minimum: (minimum)")
print("Maximum: (maximum)")

data_empty = []
mean_empty, min_empty, max_empty = analyze_numbers(data_empty)
print("List: (data_empty)")
print("Mean: (mean_empty)")
print("Minimum: (min_empty)")
print("Maximum: (max_empty)")

```

A Gemini AI interface is overlaid on the right side of the code cell, showing a prompt and a response. The prompt asks for a Python function that takes a list of numbers and returns the mean, minimum, and maximum values. The response provides the `analyze_numbers` function and includes an example of how to use it.

Task 2: Armstrong Number – AI Comparison

† Scenario : You are evaluating AI tools for numeric validation logic.

- **Prompt used (Gemini):**

"Write a Python program to check whether a given number is an Armstrong number."

- **Prompt used (Copilot):**

"Write a Python program to check whether a given number is an Armstrong number."

- **Generated code (Gemini):**

```

def is_armstrong_number(number):
    """
    Checks if a given number is an Armstrong number. An
    Armstrong number (also known as a narcissistic number,
    pluperfect digital invariant, or plus perfect number) is a
    number that is the sum of its own digits each raised to the
    power of the number of digits.
    rgs: number (int): The integer to
    check.
    Returns:
    bool: True if the number is an Armstrong number, False otherwise.
    """
    if not isinstance(number, int) or number < 0:
        return False
    num_str = str(number)
    n = len(num_str)
    sum_of_powers = 0
    for digit_char in num_str:
        digit = int(digit_char)
        sum_of_powers += digit ** n
    return sum_of_powers == number

```

- **Generated code (Copilot):**

```

#!/usr/bin/env python3
"""Armstrong number checker (task2).

Usage: python3 task2.py 153
python3 task2.py # prompts for input
"""

import argparse
import sys

def is_armstrong(n: int) -> bool:
    if n < 0:
        return False
    digits = [int(d) for d in str(n)]
    p = len(digits)
    return sum(d ** p for d in digits) == n

def main() -> None:
    parser = argparse.ArgumentParser(description='Check Armstrong numbers')
    parser.add_argument('number', nargs='?', type=int, help='integer to check')
    args = parser.parse_args()

```

```

if args.number is None:
    try:
        s = input('Enter a non-negative integer: ').strip()
        num = int(s) except (EOFError, ValueError):
        print('Invalid input', file=sys.stderr)
        sys.exit(1) else:
        num = args.number

if is_armstrong(num):
    print(f'{num} is an Armstrong number.') else:
    print(f'{num} is not an Armstrong number.')

if __name__ ==
 '__main__':
main()

```

- **Sample Input (Gemini):**

```

# Test with some numbers print(f'Is 153 an Armstrong number?
{is_armstrong_number(153)}') # Expected: True
(1^3 + 5^3 + 3^3 = 1 + 125 + 27 = 153) print(f'Is 9474 an Armstrong number?
{is_armstrong_number(9474)}') # Expected: True (9^4 + 4^4 + 7^4 + 4^4 = 6561 +
256 + 2401 + 256 = 9474) print(f'Is 9 an Armstrong number?
{is_armstrong_number(9)}') # Expected: True (9^1
= 9) print(f'Is 10 an Armstrong number? {is_armstrong_number(10)}') # Expected:
False
(1^2 + 0^2 = 1 != 10) print(f'Is 123 an Armstrong number?
{is_armstrong_number(123)}') # Expected: False

```

- **Sample Input (Copilot):**

Enter a non-negative integer: 343

- **Sample Output (Gemini):**

```

Is 153 an Armstrong number? True
Is 9474 an Armstrong number? True
Is 9 an Armstrong number? True
Is 10 an Armstrong number? False
Is 123 an Armstrong number? False

```

- **Sample Output (Copilot):**

343 is not an Armstrong number.

- **Side-by-Side Comparison Table :**

Feature	Google Gemini	GitHub Copilot
Code structure	Uses a separate function	Written directly in main logic
Readability	Very clear and modular	Simple and straightforward
Logic clarity	Easy to understand with function	Easy but less modular
Beginner friendly	High	Medium
Explanation support	Provides explanation along with code	No explanation, only code
Best use case	Learning and documentation	Fast coding inside editor

- **Side-by-Side Comparison Table :**

Analysis : Google Gemini generated a well-structured and modular solution using a function, making it suitable for learning and reuse. GitHub Copilot produced a concise and direct implementation, which is efficient for quick development within an IDE. Both tools correctly implemented the Armstrong number logic, but Gemini provided better clarity and explanation, while Copilot focused on speed and simplicity.

Conclusion : Both AI tools effectively generated correct Armstrong number checking programs. Google Gemini is more helpful for understanding and learning due to its explanations, while GitHub Copilot is ideal for rapid code generation during development.

```

def is_armstrong_number(number):
    """
    Checks if a given number is an Armstrong number.

    An Armstrong number (also known as a narcissistic number, plus-perfect digit invariant, or plus perfect number) is a number that is the sum of its own digits each raised to the power of the number of digits.

    Args:
        number (int): The integer to check.

    Returns:
        bool: True if the number is an Armstrong number, False otherwise.
    """
    if not isinstance(number, int) or number < 0:
        return False

    num_str = str(number)
    n = len(num_str)
    sum_of_powers = 0

    for digit_char in num_str:
        digit = int(digit_char)
        sum_of_powers += digit ** n

    return sum_of_powers == number

# Example Usage
# Test with some numbers
print("Is 153 an Armstrong number? (is_armstrong_number(153))") # Expected: True (1^3 + 5^3 + 3^3 = 1 + 125 + 27 = 153)
print("Is 9474 an Armstrong number? (is_armstrong_number(9474))") # Expected: True (9^4 + 4^4 + 7^4 + 4^4 = 6561 + 256 + 2401 + 256 = 9474)
print("Is 9 an Armstrong number? (is_armstrong_number(9))") # Expected: True (9^1 = 9)
print("Is 10 an Armstrong number? (is_armstrong_number(10))") # Expected: False (1^2 + 0^2 = 1 != 10)
print("Is 123 an Armstrong number? (is_armstrong_number(123))") # Expected: False
    
```

Gemini

"Write a Python program to check whether a number is an Armstrong number."
Ok, here's a Python program that defines a function to check if a number is an Armstrong number, along with some example usage.

The screenshot shows a VS Code interface with the following details:

- EXPLORER**: Shows files `task2.py`, `task2.py > ...`, `armstrong.py`, and `task2.py`.
- CODE**: The `task2.py` file is open, containing code to check if a number is Armstrong. It uses `argparse` to handle command-line arguments and `sum` with a generator expression to calculate the sum of digits raised to the power of their count.
- CHAT**: A message from the system says: "Write a Python program to check whether a number is an Armstrong number." Below it, a note says: "I'll add * task2.py with the Armstrong checker, run three example checks, then update the todo list."
- OUTPUT**: Shows terminal output for `task2.py` and `armstrong.py`.
- PROBLEMS**: No problems found.
- PORTS**: No ports listed.
- TODOS**: A todo item: "Run zsh command?".
- COMMANDS**: Buttons for "Allow" and "Skip".

Task 3: Leap Year Validation Using Cursor API

† Scenario : You are validating a calendar module for a backend system.

- **Prompt 1:**

"Write a Python program to check whether a given year is a leap year."

- **Generated code :**

```
year = int(input("Enter a year: ")) #
```

A year is a leap year if:

- It is divisible by 4 AND

- not divisible by 100, UNLESS # - it is also divisible by

400 if (year % 4 == 0 and year % 100 != 0) or (year % 400

$\equiv 0$):

```
print(f"\{year\} is a leap year.") else:
```

```
print(f"\{year\} is not a leap year.")
```

- **Prompt 2 :**

"Write an optimized Python program with proper conditions and comments to check whether a year is a leap year."

- **Generated code :**

```
year = int(input("Enter a year: "))
# A year is a leap year if:
# 1. It is divisible by 400 → leap year
# 2. Else if it is divisible by 100 → not a leap year
# 3. Else if it is divisible by 4 → leap year
# 4. Otherwise → not a leap year
```

```

if year % 400 == 0:
    print(f"{year} is a leap year.") elif year % 100 == 0:
    print(f"{year} is not a leap year.") elif year % 4 == 0:
    print(f"{year} is a leap year.") else:
    print(f"{year} is not a leap year.")

```

- **Sample Input :**

Enter a year: 2026

- **Sample Output :**

2026 is not a leap year.

- **Short Explanation of Logic :**

The first version of the code generated by Cursor AI provided basic leap year validation logic. The second prompt resulted in improved code with better readability and clear comments explaining the conditions. The optimized version is easier to understand and more suitable for real-world applications.

The screenshot shows the VS Code interface with the following details:

- File Explorer:** Shows the file `leapyear.py` with the content provided above.
- Terminal:** Shows the command `anumandar@ANUMANDLAS-MacBook-Air: /Users/anumandar@ANUMANDLAS$ python3 leapyear.py` and the output: "2026 is not a leap year."
- Python Agent:** A floating window titled "Python program for leap year che..." with the task "Write a Python program to check whether a year is a leap year." Below it, a snippet titled "Python leap year program" contains the improved code with comments.
- Status Bar:** Shows the path `/Users/anumandar@ANUMANDLAS/Downloads/leap_year.py`, the file name `leapyear.py`, and the status "Ln 10, Col 41".

The screenshot shows a code editor interface with two tabs: 'lepyear.py' and 'leap_year.py'. The left tab, 'lepyear.py', contains the following Python code:

```
# Program to check if a given year is a leap year
year = int(input("Enter a year: "))

# A year is a leap year if:
# 1. It is divisible by 400      - leap year
# 2. Else if it is divisible by 100  - not a leap year
# 3. Else if it is divisible by 4    - leap year
# 4. Otherwise                     - not a leap year

if year % 400 == 0:
    print(f"{year} is a leap year.")
elif year % 100 == 0:
    print(f"{year} is not a leap year.")
elif year % 4 == 0:
    print(f"{year} is a leap year.")
else:
    print(f"{year} is not a leap year.)
```

The right tab, 'leap_year.py', displays a 'Python program for leap year che...' snippet with the following text:

"Write an optimized Python program with clear conditions to check leap year and include comments."

Below the snippet, there are sections for 'Optimizing Python code 4s' and 'Optimized and clearly commented leap year program'. The 'Optimized and clearly commented leap year program' section contains the same Python code as the left tab, but with more descriptive comments:

```
# Program to check if a given year i
year = int(input("Enter a year: "))

# A year is a leap year if:
# 1. It is divisible by 400
# 2. Else if it is divisible by 100
# 3. Else if it is divisible by 4
# 4. Otherwise

if year % 400 == 0:
    print(f"{year} is a leap year.")
elif year % 100 == 0:
    print(f"{year} is not a leap year.)
elif year % 4 == 0:
    print(f"{year} is a leap year.)
else:
    print(f"{year} is not a leap year.)
```

At the bottom of the screen, the terminal window shows the execution of the code:

```
anumandlarithika@ANUMANDLAS-MacBook-Air leap_year.py % /usr/bin/python3 /Users/anumandlarithika/S
RU/AI_As
sisted_lab/lab2.1/leap_year.py/lepyear.py
Enter a year: 2026
2026 is not a leap year.
anumandlarithika@ANUMANDLAS-MacBook-Air leap_year.py % /usr/bin/python3 /Users/anumandlarithika/S
RU/AI_Assisted_lab/lab2.1/leap_year.py/lepyear.py
Enter a year: 2026
2026 is not a leap year.
anumandlarithika@ANUMANDLAS-MacBook-Air leap_year.py % /usr/bin/python3 /Users/anumandlarithika/S
RU/AI_Assisted_lab/lab2.1/leap_year.py/lepyear.py
Enter a year: 2024
2024 is a leap year.
anumandlarithika@ANUMANDLAS-MacBook-Air leap_year.py %
```

Task 4: Student Logic + AI Refactoring (Odd/Even Sum)

[†] Scenario : Company policy requires developers to write logic before using AI.

- **Prompt used :**
"Refactor this Python code to improve readability and efficiency."
 - **Student Code:**

$$T = (1, 2, 3, 4, 5, 6, 7)$$

even_sum = 0 odd_sum

$$= 0$$

```
for i in t: if i
```

% 2 == 0:

even sum

else:

odd

```

t = (1, 2, 3, 4, 5, 6, 7)
# Using generator expressions with sum for clarity and
efficiency even_sum = sum(i for i in t if i % 2 == 0) odd_sum =
sum(i for i in t if i % 2 != 0)

print("Sum of even numbers:", even_sum) print("Sum
of odd numbers:", odd_sum)

```

- **Sample Output :**

Sum of even numbers: 12

Sum of odd numbers: 16

```

laptop:~ ms-pythx$ python lepyear.py
2026 is not a leap year.
laptop:~ ms-pythx$ python lepyear.py
Enter a year: 2026
2026 is not a leap year.
laptop:~ ms-pythx$ python lepyear.py
Enter a year: 2024
2024 is a leap year.
laptop:~ ms-pythx$ python lepyear.py
Sum of even numbers: 12
Sum of odd numbers: 16
laptop:~ ms-pythx$ 

```
